AGA—AERODROME

March 28, 2019
EXPLANATION OF CHANGES
EFFECTIVE—MARCH 28, 2019

NOTES:
1. Editorial and format changes were made throughout the TC AIM where necessary and those that were deemed insignificant in nature were not included in the “Explanation of Changes”.

2. Effective March 31, 2016, licence differences with ICAO Annex 1 standards and recommended practices, previously located in LRA 1.8 of the TC AIM, have been removed and can now be found in AIP Canada (ICAO) GEN 1.7.

AGA

(1) **AGA—Aerodromes**

A partial review of the chapter from part 1.0 up to and including subpart 7.6 was conducted to improve the form and present the information more clearly.
Table of Contents

AGA—AERODROMES 51

1.0 GENERAL INFORMATION ............................................................................................................................. 51
  1.1 General.......................................................................................................................................................... 51
    1.1.1 Aerodrome Authority .......................................................................................................................... 51
    1.1.2 International Civil Aviation Organization (ICAO) Documents .......................................................... 51
    1.1.3 Canadian Runway Friction Index (CRFI) ........................................................................................... 51
    1.1.4 Contaminated Runway Operations ...................................................................................................... 51
    1.1.4.1 Canadian Civil Aerodromes ........................................................................................................... 51
    1.1.4.2 Department of National Defence Aerodromes .............................................................................. 51
    1.1.5 Wildlife Hazard ...................................................................................................................................... 51
  1.2 International Airports .................................................................................................................................... 51
    1.2.1 International Civil Aviation Organization (ICAO) Definitions .......................................................... 52
  1.3 Aerodrome Directory .................................................................................................................................. 52
  1.4 Aeronautical Ground Lights ....................................................................................................................... 52

2.0 AERODROMES AND AIRPORTS .................................................................................................................... 52
  2.1 General.......................................................................................................................................................... 52
    2.1.1 Registration .......................................................................................................................................... 52
    2.1.2 Certification .......................................................................................................................................... 53
  2.2 Use of Aerodromes, Airports, and Heliports .............................................................................................. 53
  2.3 Airport/Heliport/Water Airport Certification .............................................................................................. 53
    2.3.1 General ................................................................................................................................................ 53
    2.3.2 Applicability of Airport Certification .................................................................................................. 53
    2.3.3 Transport Canada's Responsibilities .................................................................................................. 53
    2.3.4 Operator's Responsibilities .................................................................................................................. 53
    2.3.5 Airport Certification Process ................................................................................................................ 53
    2.3.6 Regulatory References for Aerodrome Certification (Airport/Heliport/Water Airport) ...................... 54
  2.4 Airport/Heliport/Water Airport Certificate ................................................................................................ 54
    2.4.1 Issue .................................................................................................................................................... 54
    2.4.2 Airport Certificate Validity and Amendments ................................................................................... 54

9.2.4 Damage Hazards
9.2.5 Information for Pilots
1.0 GENERAL INFORMATION

1.1 GENERAL

All flights into, from, or over the territory of Canada and all flights landing in such territory shall be carried out in accordance with Canada’s civil aviation regulations. Aircraft arriving into or departing from the territory of Canada must first land at an aerodrome at which customs control facilities have been provided. For information about which aerodromes provide customs service, see the Canada Flight Supplement (CFS) or the Canada Water Aerodrome Supplement (CWAS), Section B, “Aerodrome/Facility Directory.” If the heading CUST (customs) appears in the left-hand column of an aerodrome table, the aerodrome is an airport of entry (AOE) with customs service.

The privileges extended to aircraft are subject to proper authorization of each flight and to whatever restrictions the Government of Canada may, from time to time, or in specific cases, deem to be warranted.

1.1.1 Aerodrome Authority

Transport Canada is responsible for the surveillance of all certified civil aerodromes in Canada. Contact information for Transport Canada’s offices can be found in GEN 1.1.1.

1.1.2 International Civil Aviation Organization (ICAO) Documents

See ICAO Annex 14, Volumes I and II.

1.1.3 Canadian Runway Friction Index (CRFI)

Many airports throughout Canada are equipped with mechanical and electronic decelerometers which are used to obtain an average of the runway friction measurement. The average decelerometer reading of each runway is reported as the CRFI. Experience has shown that results obtained from the various types of decelerometers on water, slush, wet snow, and dry snow exceeding a 1-inch depth are inaccurate, and the CRFI will not be available when these conditions are present.

Aerodromes equipped with runway friction decelerometer capability are listed in the CFS under RWY DATA.

Operational data relating to the reported average CRFI and the methods to be used when applying these factors to aircraft performance are presented in AIR 1.6.

1.1.4 Contaminated Runway Operations

1.1.4.1 Canadian Civil Aerodromes

At Canadian aerodromes where snow removal and ice control operations are conducted, assessment and mitigation procedures are carried out to the extent that is practicable in order to provide movement surfaces that will permit safe operational use.

Pilots who are confronted with conditions produced by the ever-changing Canadian climate must be familiar with and anticipate the overall effect of contaminated runways on aircraft handling characteristics in order to take any corrective actions considered necessary for flight safety.

In general terms, whenever a contaminant, such as water, snow, or ice, is present on the runway surface, the effective coefficient of friction between the aircraft tire and runway is reduced. However, the accelerate-stop distance, landing distance, and crosswind limitations contained in the AFM are demonstrated in accordance with specified performance criteria on bare and dry runways during the aircraft certification flight test program and are thus valid only when the runway is bare and dry.

As a result, the stop portion of the accelerate-stop distance will increase, the landing distance will increase, and a crosswind will present directional control difficulties.

It is therefore expected that pilots will take all necessary action, including the application of any appropriate adjustment factor to calculate stopping distances for their aircraft as may be required based on the RSC and CRFI information.

1.1.4.2 Department of National Defence Aerodromes

Snow removal and ice control policy and procedures at Canadian military aerodromes are similar to those of Canadian civil aerodromes; however, the military aerodrome operator might not use the same type of friction measuring equipment to obtain the average runway friction index.

1.1.5 Wildlife Hazard

Certified airports in Canada are required to have a plan to identify and control the hazards wildlife (birds and other animals) present to flight operations. The risk of wildlife strikes may increase during spring and autumn migrations; however, airports can be subject to hazardous wildlife year-round. Pilots should monitor ATIS for information concerning this hazard.

For more information on wildlife hazards, migratory birds, and wildlife-strike reporting, see AIP Canada (ICAO) ENR 5.6.

1.2 INTERNATIONAL AIRPORTS

Some airports are designated “international airport” by Transport Canada to support international commercial air transport. See AIP Canada (ICAO) GEN 1.2.2.1 for information on international commercial flights.
1.2.1 International Civil Aviation Organization (ICAO) Definitions

**International Scheduled Air Transport, Regular Use (RS):** An aerodrome which may be listed in the flight plan as an aerodrome of intended landing.

**International Scheduled Air Transport, Alternate Use (AS):** An aerodrome specified in the flight plan to which a flight may proceed when it becomes inadvisable to land at the aerodrome of intended landing.

**International General Aviation, Regular Use (RG):** All aircraft other than those operated on an international air service.

**NOTE:** Any of the listed regular aerodromes may be used as a regular or alternate aerodrome.

1.3 Aerodrome Directory

Complete general data on Canadian aerodromes is listed in the Canada Flight Supplement (CFS). ICAO Type A Charts are available from NAV CANADA’s Aeronautical Information Management (AIM) (see MAP 4.2.1 and <www.navcanada.ca/en/products-and-services/Pages/aeronautical-information-charts-ICAO-type-a-charts.aspx>).

1.4 Aeronautical Ground Lights

Information on aeronautical ground lights can be found in the Canada Flight Supplement (CFS) under the LIGHTING entry in the table of the aerodrome they serve or on visual flight rules (VFR) navigational charts.

2.0 Aerodromes and Airports

2.1 General

An aerodrome is defined by the Aeronautics Act as:

*Any area of land, water (including the frozen surface thereof) or other supporting surface used, designed, prepared, equipped or set apart for use either in whole or in part for the arrival, departure, movement or servicing of aircraft and includes any buildings, installations and equipment situated thereon or associated therewith.*

This has a very broad application for Canada where there are no general restrictions preventing landings or takeoffs. There are defined exceptions, but, for the most part, all of Canada can be an aerodrome.

Rules for operating an aerodrome are provided in Part III of the Canadian Aviation Regulations (CARs) under Subpart 301. The objective is to define the minimum safety standards that must be offered as well as to make provision for inspection by the Minister. Aerodrome operators are encouraged, in the interest of aviation safety, efficiency, and convenience, to improve their aerodromes beyond the basic regulatory requirements using, as guidelines, the standards and recommended practices applicable for the certification of aerodromes as airports, heliports, or water airports. Aerodrome users are, however, reminded that the improvement of aerodrome physical characteristics, visual aids, lighting, and markings beyond the basic regulatory requirements for aerodromes stated in CAR 301 is a matter of individual aerodrome operators’ initiative. Such improvements do not require regulatory compliance, nor are those improvements inspected or certified in accordance with the standards and recommended practices applicable for the certification of aerodromes as airports, heliports, or water airports.

2.1.1 Registration

Subsection 301 also regulates the “Registration” process, which is used to publish and maintain information on an aerodrome in the CFS or the CWAS. The regulation specifies that an aerodrome operator can expect:

(a) to have their aerodrome registered in the appropriate publication when they provide the necessary information with respect to location, markings, lighting, use, and operation of the aerodrome;

(b) to have their aerodrome denied registration in the appropriate publication if they do not meet the aerodrome regulatory requirements for markers and markings, warning notices, wind direction indicator, and lighting;

(c) to assume responsibility of immediately notifying the Minister of any changes in the aerodrome’s published information regarding its location, markings, lighting, use, or operation; and

(d) to have their aerodrome classed as a registered aerodrome when it is published in the CFS or CWAS.

**NOTE:**

No aerodrome operator is obliged by these regulations to have information published in the CFS or CWAS. The Minister may choose not to publish information for a site that is considered to be hazardous to aviation safety.

In addition to the initial inspection during the application for registration, other inspections are done on an as-required basis, once the aerodromes are registered, to verify their compliance with CARs and the accuracy of their information as it is published in the CFS or the CWAS. Such information, however, is only published for the convenience of the pilot and should be confirmed through contact with the aerodrome operator before the pilot uses a site.
2.1.2 Certification

Besides “aerodrome” and “registered aerodrome”, other terms include “airport”, “heliport”, and “water airport”. These are aerodromes for which a certificate has been issued under Subpart 302 of the CARs or Subpart 305 for heliports. The objective is to protect those, such as the fare-paying public and residents in the vicinity of an airport, who do not have the knowledge or ability to protect themselves and who could thus be affected by unsafe operations. This is achieved by ensuring sites are inspected periodically for compliance with Transport Canada standards for obstacle limitation surfaces, physical characteristics, marking, lighting, maintenance procedures, emergency response services, etc., which have been recorded in the Airport/Heliport Operations Manual. The current information is to be communicated to all interested aircraft operators through the CFS, the CAP, NOTAMs, and voice advisories, as applicable. See AGA 2.3 for more information about aerodrome certification.

2.2 USE OF AERODROMES, AIRPORTS, AND HELIPORTS

An aerodrome, airport, or heliport listed in the Canada Flight Supplement (CFS) or the Canada Water Aerodrome Supplement (CWAS) that does not require prior permission of the aerodrome or airport operator for aircraft operations is called a public-use aerodrome, airport, or heliport.

An aerodrome, airport, or heliport that can be listed in the CFS or CWAS but whose use can be limited is called a private-use aerodrome. This can include:

(a) Prior Permission Required (PPR): The aerodrome operator’s permission is required prior to use. All military aerodromes require PPR for Civilian aircraft.

(b) Prior Notice Required (PN): The aerodrome operator owner or operator is to be notified prior to use so that current information on the aerodrome may be provided.

NOTES:
1. Pilots and aerodrome operators are reminded that trespass restrictions are not applicable to aircraft in distress.
2. Pilots intending to use a non-certified aerodrome are advised to obtain current information from the aerodrome operator concerning operating conditions prior to using that aerodrome for aircraft operations.

2.3 AIRPORT/HELIPORT/WATER AIRPORT CERTIFICATION

2.3.1 General

Transport Canada is responsible for the regulatory development and compliance oversight in support of a safe national air transportation system. Therefore, airports supporting commercial operations involving the carrying of passengers must meet accepted safety standards. The airport operator that holds an airport certificate testifies that the aerodrome meets such safety standards. Where variances from airport certification safety standards are required, studies will be undertaken to devise offsetting procedures, which will provide equivalent levels of safety.

2.3.2 Applicability of Airport Certification

The requirement for aerodrome certification applies to:

(a) any aerodrome that is located within the built-up area of a city or town;

(b) any land aerodrome that is used by an air operator for the purpose of a scheduled service for the transport of passengers; and

(c) any other aerodrome, where the Minister is of the opinion that it is in the public interest for that aerodrome to meet the requirements necessary for the issuance of an airport certificate because it would further the safe operation of the aerodrome.

Exemptions include:

(a) military aerodromes; and

(b) aerodromes for which the Minister has written an exemption and an equivalent level of safety is defined.

2.3.3 Transport Canada's Responsibilities

The responsibilities of Transport Canada include:

(a) developing safety standards, policies, and criteria for elements such as, but not limited to:
   (i) physical characteristics of the manoeuvring area, including separations,
   (ii) marking and lighting, and
   (iii) obstacle limitation surfaces in the vicinity of airports, heliports and water airports;

(b) reviewing aeronautical studies where variances from airport certification safety standards are required;

(c) certifying and inspecting against the requirements and conditions of the respective operations manuals (for airports, heliports, or water airports); and

(d) verifying, amending, and relaying, as appropriate, pertinent airport/heliport/water airport information to be identified in the appropriate AIS publications.

2.3.4 Operator’s Responsibilities

The responsibilities of the operator of an airport/heliport/water airport include, but are not limited to:
(a) complying with the applicable regulations and standards in Part III of CARs;

(b) completing and distributing an approved operations manual;

(c) maintaining the facility in accordance with the requirements specified in the airport/heliport/water airport operations manual; and

(d) advising Transport Canada and aircraft operators whenever services or facilities fall below requirements prescribed in the operations manual or differ from the information published in the aeronautical publications for their aerodrome.

2.3.5 Airport Certification Process

Airport certification is a process whereby Transport Canada certifies that an aerodrome meets airport certification safety standards and that aerodrome data, as provided by the owner or operator and as confirmed by Transport Canada inspectors at the time of certification, is correct and published in the appropriate aeronautical information publications. When these requirements are met, an airport certificate is issued. The airport certificate documentation includes:

(a) the airport certificate, which certifies that the airport meets required standards at the time of issuance; and

(b) the operations manual, which details the airport specifications, facilities, and services, and specifies the responsibilities of the operator for the maintenance of airport certification standards. The operations manual is a reference for airport operations and inspections, which ensures that variances from airport certification safety standards and the resulting conditions of airport certification are approved.

2.3.6 Regulatory References for Aerodrome Certification (Airport/Heliport/Water Airport)

The regulatory authority for airport, heliport, and water airport certification is Subpart 302 of the CARs. The regulatory authority for heliport certification can be found under Part III of the CARs, which includes reference to the respective compliance standards for aerodrome certification. Depending on the date on which the certificate was initially issued, some aerodrome operators may be complying with previous versions of the certification standards.

2.4 Airport/Heliport/Water Airport Certificate

2.4.1 Issue

A certificate will be issued when an inspection confirms that all requirements for airport certification have been met, including the following:

(a) where variance from the certification standards exists, measures have been implemented to provide for an equivalent level of safety; and

(b) the operations manual has been approved by the Regional Director, Civil Aviation.

2.4.2 Airport Certificate Validity and Amendments

The airport certificate is a legal aviation document that remains valid as long as the airport is operated and maintained in accordance with the operations manual. Periodic inspections are conducted to verify continued conformity to the certification standards and conditions specified in the operations manual.

Transport Canada may make amendments to the conditions applicable to the issuing of an airport certificate when:

(a) an approved variance from certification standards and a change in the conditions of certification are required;

(b) there is a change in the use or operations of the airport; and

(c) it is requested by the holder of the airport certificate.

3.0 RUNWAY CHARACTERISTICS

3.1 Runway Length and Width

Runways are generally dimensioned to accommodate an aircraft considered to be the critical aircraft. Critical aircraft is defined in the fifth edition of the Transport Canada publication titled Aerodrome Standards and Recommended Practices (TP 312) as “the aircraft identified as having the most demanding operational requirements with respect to the determination of movement area dimensions, and other aerodrome physical characteristics at the aerodrome or part thereof”. To identify the critical aircraft, flight manual performance data of a variety of aircraft is examined. Once the critical aircraft has been determined, the longest distance determined after analyzing both take-off and landing performance is used as the basis for runway dimensions. Generally, the runway width can be increased by a maximum of 60 m as a function of length.
3.2 Runway Strip

Each runway is bounded by a runway strip on its sides and ends to protect aircraft that overfly the runway at very low altitudes during a balked approach for landing. This is achieved by restricting the presence of objects to only those that must be in proximity of the runway as part of normal operations and by prescribing frangibility requirements.

3.3 Runway Safety Area

Each runway is bounded by a prepared area on its sides and ends, within the dimensions of the runway strip. It is graded to prevent catastrophic damage to aircraft leaving the runway sides.

3.4 Runway End Safety Area (RESA)

On some runways there may be an area, at the end and beyond the runway strip, prepared to reduce the severity of damage to an aircraft overrunning or undershooting the runway.

3.5 Runway Threshold Displacement

Occasionally, natural and human-made obstacles penetrate the obstacle limitation surfaces of the approach paths to runways.

To ensure that a safe clearance from these obstacles is maintained, it is necessary to displace the threshold upwind from the adjacent runway end where the approach slope cannot be raised. In the case of runways for which instrument approach procedures (IAP) are published in the Canada Air Pilot (CAP), the usable runway distances for landings and takeoffs are specified as declared distances. The displacements are also depicted on the aerodrome or airport diagram in both the CAP and the Canada Flight Supplement (CFS). For other runways that do not have approaches published in the CAP, the requisite data is given in the CFS. Where a threshold is displaced, it is marked as shown in AGA 5.4.1, Figure 5.5.

When the portion of the runway preceding the threshold is marked with arrows (see AGA 5.4.1), it is permissible to use that portion of the runway for taxiing, takeoff, and landing roll-out from the opposite direction. When taking off from the end opposite the threshold, pilots should be aware of the fact that there are obstacles present that have penetrated above the approach slope leading to the physical end of the runway and have resulted in the threshold being displaced. In some cases, this may result in the publication of a specified climb and/or visibility.

3.6 Runway Turn Pad

Some runways have thresholds that are not served directly by taxiways. In such cases, there may be a runway turn pad, a widened area that can be used to facilitate turnaround. Pilots are cautioned that these pads do not give sufficient clearance from the runway edge and thus cannot be used for holding while other aircraft are using the runway.

3.7 Blast Pad

A blast pad is defined in the Aerodrome Standards and Recommended Practices (TP 312) as “an area before the threshold that is prepared to resist erosion arising from jet exhaust or propeller wash.” When over 60 m in length, this entire paved, non-load-bearing surface is marked with yellow chevrons, as shown in AGA 5.4.2, Figure 5.6.

3.8 Stopway

A stopway is defined in the Aerodrome Standards and Recommended Practices (TP 312) as “a rectangular area on the ground at the end of take-off run available prepared as a suitable area in which an aeroplane can be stopped in the case of a rejected takeoff.” Where paved, it is marked over its entire length with yellow chevrons (when its length exceeds 60 m) as shown in AGA 5.4.2, Figure 5.6, and is lit with red edge and end lights in the take-off direction. Its length is included in the accelerate-stop distance available (ASDA) declared for the runway.

3.9 Clearway

A clearway is defined in the Aerodrome Standards and Recommended Practices (TP 312) as “a defined rectangular area over land or water under the control of the aerodrome operator, selected as a suitable area over which an aircraft may make a portion of its initial climb to a specified height”.

3.10 Declared Distances

The Canada Air Pilot (CAP) provides information on declared distances, which are defined in the fifth edition of the Aerodrome Standards and Recommended Practices (TP 312) as follows:

“The distances that the aerodrome operator declares available for aircraft take-off run, take-off distance, accelerate stop distance, and landing distance requirements. The distances are categorized as follows:

(a) Take-off run available (TORA): The length of runway declared available and suitable for the ground run of an aircraft taking off.

(b) Take-off distance available (TODA): The length of the takeoff run available plus the length of the clearway, if provided.
(c) Accelerate-stop distance available (ASDA): The length of the takeoff run available plus the length of the stopway, if provided.

(d) Landing distance available (LDA): The length of the runway available and suitable for the ground run of an aircraft landing.”

3.11 RAPID-EXIT TAXIWAYS

To reduce the aircraft runway occupancy time, some aerodromes or airports provide rapid-exit taxiways, which are connected to the runway at an angle of approximately 30 degrees.

3.12 RUNWAY AND TAXIWAY BEARING STRENGTH

The bearing strength of some aerodrome or airport pavement surfaces (runways, taxiways, and aprons) that is required to withstand continuous use by aircraft of specific weights and tire pressures has been assessed at specific locations. The Transport Canada (TC) pavement load rating (PLR) and International Civil Aviation Organization (ICAO) pavement classification number (PCN) define the weight limits at or below which the aircraft may operate on pavements without prior approval of the aerodrome or airport authority. The tire pressure and aircraft load rating (ALR)/aircraft classification number (ACN) must be equal to or less than the PLR/PCN figures published for each aerodrome or airport. Aircraft exceeding the published load restrictions may be permitted for limited operations following an engineering evaluation by the airport operator. Requests to permit such operations should be forwarded to the airport operator and should include the aircraft type, operating weight, and tire pressure, as well as the frequency of the proposed operation and the pavement areas required at the aerodrome or airport.

3.12.1 Pavement Load Rating Charts

Operators who require information about the aircraft weight limitations in effect at an aerodrome or airport can contact the aerodrome or airport operator.

3.13 HELIPORTS

Because of the unique operational characteristics of helicopters, a heliport’s physical characteristics differ significantly from the physical characteristics of other aerodromes. For instance, a heliport does not require a runway, but instead requires a final approach and take-off area (FATO). The FATO is 1.5 times larger than the longest helicopter for which the heliport is certified and is surrounded by a safety area, which is to be kept free of obstacles, other than visual aids.
H3 heliports have suitable and available emergency landing areas within 625 m of the FATO and no obstacles that penetrate the OLSs; they may therefore be used by single- or multi-engine helicopters. Heliport classifications are specified in the CFS.

3.13.3 Heliport Operational Limitations

All heliports have three operational limitations. The limitations for each specific heliport are listed in the CFS.

The load-bearing strength shall be identified for each elevated or rooftop FATO or floating supporting structure. Surface-level heliports do not need to list a load-bearing strength.

The maximum helicopter overall length shall be identified for each FATO. This is calculated as the width or diameter of each FATO, divided by 1.5. This number represents the largest size of helicopter for which the FATO is certified.

The heliport category (instrument or non-instrument) and classification, as detailed in AGA 3.13.2, above, shall also be listed.

4.0 OBSTACLE RESTRICTIONS

4.1 GENERAL

The safe and efficient use of an aerodrome, airport, or heliport can be seriously compromised by the presence of obstacles within or close to the take-off or approach areas. The airspace in the vicinity of take-off or approach areas, which is to be maintained free from obstacles so as to facilitate the safe operation of aircraft, is defined for the purpose of:

(a) regulating aircraft operations where obstacles exist;

(b) removing obstacles; or

(c) preventing the creation of obstacles.

4.2 OBSTACLE LIMITATION SURFACES (OLS)

4.2.1 General

An OLS establishes the limit to which objects may project into the airspace associated with an airport so that aircraft operations at the airport may be conducted safely. It includes an approach surface, a take-off surface, and a transitional surface.

4.2.2 Heliports

Heliports are normally served by two approach and departure paths. In some instances, they only have one approach and departure path and will then require a transitional surface.

4.3 AIRPORT ZONING REGULATIONS

4.3.1 General

An airport zoning regulation is a regulation applicable to a given airport pursuant to section 5.4(2) of the Aeronautics Act that imposes restrictions on land use, including vertical development, with the objective of protecting an airport’s current and future accessibility, usability, and viability by:

(a) preventing lands adjacent to or in the vicinity of a federal airport or an airport site from being used or developed in a manner that is, in the opinion of the Minister, incompatible with the operation of an airport;

(b) preventing lands adjacent to or in the vicinity of an airport or airport site from being used or developed in a manner that is, in the opinion of the Minister, incompatible with the safe operation of an airport or aircraft; and

(c) preventing lands adjacent to or in the vicinity of facilities used to provide services relating to aeronautics from being used or developed in a manner that would, in the opinion of the Minister, cause interference with signals or communications to and from aircraft or to and from those facilities.
NOTE:
An airport zoning regulation applies only to land outside the boundary of the airport it protects. Obstacles within an airport boundary must not penetrate an OLS for the runway(s) involved unless the obstacle is exempted as a result of an aeronautical study.

4.3.2 Airports Where Zoning Regulations Are in Effect

A list of airports where airport zoning regulations are in effect is maintained in the Regional Aerodrome Safety office and online on the Aeronautics Act page of the Department of Justice Web site, under the heading “Regulations made under this Act”.

5.0 MARKERS, MARKINGS, SIGNS, AND INDICATORS

5.1 Aircraft Take-off or Landing Area Boundary Markers

The take-off or landing area boundaries of aerodromes without prepared runways are indicated by conical- or gable-type markers (highway-type cone markers are acceptable) or by evergreen trees in winter. No boundary markers are required if the entire movement area is clearly delineated from that of the surrounding ground. The markers are typically coloured international orange and white or solid international orange.

5.2 Air Taxiway Edge Markers

The edges of the air taxiway route are indicated by markers 35 cm in height that consist of three horizontal bands of equal size arranged vertically. The top and bottom bands are yellow and the middle one is green.

5.3 Seaplane Dock Markers

Seaplane docks are marked to facilitate their identification. The dock is marked with an equilateral triangle measuring 2.4 m on each side. The dock to which this marker is affixed also has red and white side markings.
5.4 **Runway Markings**

Runway markings vary depending on the runway’s length, width, surface type, and, if available, aircraft group number (AGN). They are described in detail in Transport Canada’s *Aerodrome Standards and Recommended Practices* (TP 312).

Where an aiming point marking is provided, it is white and located at a specific distance from the threshold per Table 5.1 below.

<table>
<thead>
<tr>
<th>Declared landing distance available (LDA)</th>
<th>Location of aiming point marking distance from threshold (m)</th>
</tr>
</thead>
<tbody>
<tr>
<td>less than 800 m</td>
<td>150</td>
</tr>
<tr>
<td>800 m up to but not including 1200 m</td>
<td>250</td>
</tr>
<tr>
<td>1200 m up to but not including 2400 m</td>
<td>300</td>
</tr>
<tr>
<td>2400 m or more</td>
<td>400</td>
</tr>
</tbody>
</table>

Where touchdown zone (TDZ) markings are provided, they are white and found in pairs in accordance with Table 5.2 and Figure 5.4 below. The location of pairs of TDZ markings is based on a horizontal spacing of 150 m. However, aiming point markings take precedence over TDZ markings; therefore, a pair of TDZ markings is omitted if it would otherwise fall within 50 m of the aiming point marking.

**NOTE:** When the threshold must be displaced for a relatively short period of time, painting a temporary threshold bar is impractical. Instead, flags, cones, or wing bar lights are installed to indicate the position of the displaced threshold. A NOTAM or voice advisory warning of the temporary displacement will contain a description of the markers and the expected duration of the displacement in addition to the length of the closed portion and the remaining usable runway.

### 5.4.1 Displaced Threshold Markings

![Figure 5.5—Displaced Threshold Markings](image)

**Figure 5.5—Displaced Threshold Markings**

### 5.4.2 Stopway Markings

The paved area preceding a runway threshold prepared, maintained, and declared as a stopway is marked with yellow chevrons when its length exceeds 60 m. This area is not available for taxiing, the initial take-off roll, or the landing rollout. The chevron markings may also be used on blast pads.

<table>

5.4.3 Runway Holding Position Markings

Runway holding position markings are provided near all runway/taxiway intersections and runway/runway intersections to protect the operational environment of the runway in use. They may also be established at other locations to protect the arrival and departure flight paths to a runway.

The standard runway holding position marking consists of two solid and two dashed lines as depicted in Figure 5.7.

Some airports may have multiple runway holding position markings on a given taxiway. These additional markings are commonly referred to as having a ladder-type pattern as depicted in Figure 5.7. It is important to note that in all cases, the runway holding position marking nearest to the runway will be the standard presentation.

5.5 HELIPORTS

5.5.1 Heliport Touchdown and Lift-Off Area (TLOF) Marking

When the perimeter of the TLOF is not otherwise obvious, it will be marked by a solid white line.

5.5.2 Safety Area Markers

The safety area that surrounds the FATO may be indicated by gable, conical, or other types of suitable markers or markings.

5.5.3 Heliport Identification Markings

Heliports are identified by a white capital letter “H” centred within the TLOF. Where it is necessary to enhance the visibility of the letter “H”, it may be centred within a dashed triangle. Hospital heliports are identified by a red capital letter “H” centred within a white cross.

The letter “H” will be oriented with magnetic north, except in the area of compass unreliability, where it will be oriented with true north.

5.5.4 Final Approach and Take-Off Area (FATO) Markers

Where practicable, the boundary of the FATO will be indicated by gable, conical, or other types of suitable markers. The markers shall be frangible and shall not exceed a height of 25 cm. An aiming point marking will be provided and located in the centre of the FATO, where practicable.
the direction of the helicopter parking position is not obvious, an indicator will show its direction.

5.5.5 Helicopter Parking Position Markings

Helicopter parking position markings consist of two concentric yellow circles. The diameter of the outer circle shall not be less than 1.2 times the overall length of the longest helicopter for which the helicopter parking position is certified. The diameter of the inner circle is one-third of the size of the outer circle. An “H” marking will be centred within the inner circle.

5.5.6 Approach and Take-Off Direction Indicator Markings

There may be heliports where, due to nearby obstacles or noise-sensitive areas, approach and take-off directions are designated. The direction of the approach and take-off paths is indicated by a double-headed arrow, showing their inbound and outbound directions. The arrows are located beyond the edge of the safety area or on the aiming point marking.

5.6 CLOSED MARKINGS

The closed portion of the runway may be shown on the aerodrome or airport diagram in the Canada Flight Supplement (CFS) and the Canada Air Pilot (CAP) for identification purposes; however, declared distances will only include runway length starting at the new threshold position.

Runways, taxiways, helicopter final approach and take-off areas (FATO), and other helicopter areas that are closed to operations are marked by “Xs”, as shown in Figure 5.11. Snow-covered areas may be marked by “Xs” using conspicuously coloured dye.

“Xs” applied to runways are white in colour and placed within a maximum spacing of 300 m of each other. For taxiways, the “Xs” are yellow in colour and placed at each end of the closed portion.

For helicopter FATOs, the “X” is white in colour. For other helicopter areas such as helicopter parking positions, the “X” is yellow in colour.

5.7 UNSERVICEABLE AREA MARKERS

Unserviceable portions of the movement area other than runways and taxiways are delineated by markers such as marker boards, cones, or red flags and, where appropriate, a flag or suitable marker is placed near the centre of the unserviceable area. Red flags are used when the unserviceable portion of the movement area is sufficiently small for it to be by-passed by aircraft without affecting the safety of their operations.
5.8 AIRSIDE SIGNS

5.8.1 General

The primary purpose of airside signs is to ensure the safe and expeditious movement of aircraft on the aprons, taxiways, and runways by providing direction and information to pilots.

The two main categories of airside signs are information signs and mandatory instruction signs, differentiated by using black/yellow and red/white colour combinations, respectively.

5.8.2 Information Signs

Information signs identify a specific destination, location, frequency, or routing information to pilots. The inscriptions incorporate arrows, numbers, letters, or pictographs to convey instructions or to identify specific areas.

(a) Location Sign: A location sign has a yellow inscription on a black background and is used to identify the taxiway that the aircraft is on or entering. A location sign never contains arrows.

(b) Direction Sign: A direction sign has a black inscription on a yellow background and is used to identify the intersecting taxiways toward which an aircraft is approaching. The sign is, whenever practicable, positioned on the left-hand side of the taxiway and prior to the intersection. A direction sign will always contain arrows to indicate the approximate angle of intercept. Direction signs are normally used in combination with location signs to provide the pilot with position information. The location sign will be in the centre or datum position. In this configuration, all left turn direction signs are located to the left of the location sign and all right turn direction signs are located to the right of the location sign.

The only exception to this rule is for a simple “T” intersection, where the information sign is located on the opposite side (the top of the “T”) of the intersection, facing the taxiway.

When a taxiway continues through the intersection and changes heading by more than 25° or changes its designation, a direction sign will indicate this fact.

(c) Runway Exit Signs: A runway exit sign has a black inscription on a yellow background and is used to identify a taxiway that exits a runway. The sign is positioned prior to the intersection on the same side of the taxiway as the exit. The sign will always contain an arrow and will indicate the approximate angle at which the taxiway intersects the runway. When a taxiway crosses a runway, a sign will be positioned on both sides of the runway. Runway exit signs may be omitted in cases where aircraft do not normally use the taxiway to exit or in cases of one-way taxiways.

(d) Destination Signs: A destination sign has a black inscription on a yellow background and is used to provide general guidance to points on the airfield. These signs will always contain arrows. The use of destination signs will be kept to a minimum. Airports with a good direction sign layout will have little need for destination signs.

(e) Other Information Signs: Other information signs have a black inscription on a yellow background and include information such as stand identification, parking areas and frequency.

5.8.3 Mandatory Instruction Signs

Mandatory instruction signs are used to identify runway designations, holding positions, NO-ENTRY areas, and obstacle-free zones, where pilots must receive further ATC clearance to proceed. At uncontrolled aerodromes, pilots are required to hold at points marked by these signs until they have ascertained that there is no air traffic conflict. Mandatory instruction signs have white letters, numbers, or symbols against a red background and are installed on both sides of a taxiway or runway, unless it is physically impossible to do so and provided that an equivalent painted sign marking is provided on the taxiway or runway.

(a) Runway Designation Sign: A runway designation sign is installed at all taxiway/runway and runway/runway intersections at certified aerodromes. A runway designation sign is used for runways certified for VFR, IFR non-precision, and take-off operations. The sign,
when installed at the runway end, shows the designator of the departure runway. Signs installed at locations other than the runway ends shall show the designator for both runways. A location sign is positioned in the outboard position beside the runway designator.

In the following examples, “A” shows that an aircraft is located on Taxiway “A” at the threshold of Runway 34. The second example has the aircraft on Taxiway “C” at the intersection of Runway 34/16. The threshold of Runway 34 is to the left and Runway 16 to the right.

**Figure 5.14—Examples of Runway Designation Signs**

For airports located within the area of compass unreliability, the same rules apply, except that the sign shows the exact true azimuth of the runway(s) as a three-digit number.

**Figure 5.15—Runway Designation Sign in Area of Compass Unreliability**

(b) **Category I, Category II, and Category III holding position signs**: CAT I, CAT II, and CAT III holding position signs are installed to protect the ILS critical area during IFR precision operations. A sign is installed on each side of the taxiway in line with the CAT I/II/III hold position marking. The inscription will consist of the designator of the runway and the inscription CAT I, CAT II, CAT III, or a combination, as appropriate.

**NOTE:**
Where only one holding position is necessary for all categories of operation, a CAT I/II/III sign is not installed. In all cases, the last sign before entering a runway will be the runway designation sign.

(c) **NO-ENTRY sign**: A NO-ENTRY sign, as shown in Figure 5.16, will be located at the beginning and on both sides of the area to which entrance is prohibited.

(d) **APCH sign**: Located at a runway holding position that has been established for the protection of approach or departure paths. The airport configuration may be such that these holding positions are located on runways or taxiways.

**Figure 5.16—Mandatory Instruction Signs**

- Runway designation of a runway extremity
  - Indicates a runway holding position at a runway extremity.
  - Note: For single runway designations, the width of the sign is increased to make the red background more conspicuous.

- Runway designation of both extremities of a runway
  - Indicates runway holding position located at other than a runway extremity.
  - A runway holding position sign at a runway/runway intersection does not include a location sign.

- 27-09 33-15
  - Indicates a runway holding position at runway/runway/taxiway, or runway/runway/runway intersection.

- ILS Category I hold position
  - Indicates a Category I runway holding position at the threshold of a runway (e.g. runway 25).

- ILS Category II hold position
  - Indicates a Category II runway holding position at the threshold of a runway (e.g. runway 25).

- ILS Category III hold position
  - Indicates a Category III runway holding position at the threshold of a runway (e.g. runway 25).

- ILS Category II and III hold position
  - Indicates a joint Category II and III runway holding position at the threshold of a runway (e.g. runway 25).

- SD ENTRY
  - Indicates that entry to an area is prohibited.

- Approach or departure surface holding position
  - Indicates a runway holding position that has been established for the protection of an approach or departure surface CILS to a runway.

5.8.4 **Illumination of Airside Signs**

Airside signs are illuminated at airports that are used at night or in low visibility. Signs, which are illuminated internally, may be of two types. One type has a sign face constructed from material, such as plexiglass, which permits the entire sign face to be illuminated. The other type has a sign face that incorporates imbedded fibre optic bundles that illuminate the individual letters, numbers, and arrows, not the face of the sign. At night or in low visibility, pilots approaching a fibre optic sign will see RED illuminated characters on mandatory instruction signs, YELLOW characters on a location sign, and WHITE characters on all other information signs.

5.9 **Wind Direction Indicators**

At aerodromes that do not have prepared runways, the wind direction indicator is usually mounted on or near some conspicuous building or in the vicinity of the general aircraft parking area.

Runways greater than 1 200 m in length will have a wind direction indicator for each end of the runway. It will be typically located adjacent to the touchdown zone, 60 m outward from the edge of the runway, and clear of the obstacle-free zone.

Runways 1 200 m in length and shorter will have a wind direction indicator located centrally on the aerodrome or near each end of the runway, typically positioned in proximity to the aiming point markings.

For night operations the wind direction indicator will be illuminated.
NOTE:
At aerodromes certified as airports, a dry standard wind direction indicator will react to wind speed as follows:

Table 5.3—Wind Indicator Angle Based on Wind Speed

<table>
<thead>
<tr>
<th>Wind Speed</th>
<th>Wind Indicator Angle</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 kt or above</td>
<td>Horizontal</td>
</tr>
<tr>
<td>10 kt</td>
<td>5° below horizontal</td>
</tr>
<tr>
<td>6 kt</td>
<td>30° below horizontal</td>
</tr>
</tbody>
</table>

At aerodromes not certified as airports, non-standard wind indicator systems, which could react differently to wind speed, may be in use.

6.0 OBSTRUCTION MARKING AND LIGHTING

6.1 GENERAL

Where an object, regardless of its height, has been assessed as constituting an obstacle to air navigation per Canadian Aviation Regulation (CAR) 601.23(1), it requires marking and/or lighting in accordance with the standards specified in CAR Standard 621.

6.2 STANDARDS

*Canadian Aviation Regulations* (CAR) 601.23–601.27 provide regulations regarding marking and lighting of obstacles to air navigation. The following objects must be marked and/or lighted in accordance with the standards specified in CAR Standard 621:

(a) any object penetrating an airport obstacle limitation surface (OLS) as specified in Chapter 4 of *Aerodrome Standards and Recommended Practices* (TP 312);

(b) any object greater than 90 m above ground level (AGL) within 6 km of the geographical centre of an aerodrome;

(c) any object greater than 90 m AGL within 3.7 km of the imaginary centreline of a recognized visual flight rules (VFR) route, including but not limited to a valley, a railroad, a transmission line, a pipeline, a river, or a highway;

(d) any permanent catenary wire crossing where any portion of the wires or supporting structures exceeds 90 m AGL;

(e) any object greater than 150 m AGL; and

(f) any other object, other than the above, deemed by the Minister to represent a likely hazard to aviation safety.

6.3 AERONAUTICAL EVALUATION

A person planning to erect or modify an obstruction, namely a building, structure, or object, including a moored balloon or kite, either permanently or temporarily, is required to contact the appropriate regional Transport Canada Civil Aviation office at least 90 days prior to erection and provide the information on the planned obstruction, using an *Aeronautical assessment form for obstruction marking and lighting* (Form 26-0427E is available in Transport Canada's forms catalogue at <http://wwwapps.tc.gc.ca/Corp-Serv-Gen/5_Forms-Formulaires/search>.

6.4 MARKING

Day marking of obstructions that are 150 m above ground level (AGL) in height or less, such as poles, chimneys, antennas, and cable tower support structures, may consist of alternate bands of aviation orange and white paint. A checkerboard pattern may be used for water tanks, as shown in Figure 6.1. Where a structure is provided with medium or high-intensity white flashing strobe lighting systems that are operated during the day, paint marking of the structure may be omitted.

Figure 6.1—Storage Tank Marking

The roof or a portion of it may be solid orange where the perpendicular projection is equal to or less than 1.5 m.

6.5 LIGHTING

Lighting is installed on obstructions in order to warn pilots of a potential collision.

The required intensity for this lighting is based upon an acquisition distance from which the pilot would recognize the lighting as identifying an obstruction, and be able to initiate evasive action to miss the obstruction by at least 600 m. For an aircraft operating at 165 knots indicated airspeed (KIAS), the acquisition distance is 1.90 km. For an aircraft operating between 165 and 250 KIAS, the acquisition distance is 2.38 km.
A variety of lighting systems are used on obstructions. Table 6.1 indicates the characteristics of light units according to their name or designation. Although these designations are similar to those of the Federal Aviation Administration (FAA), the photometric characteristics (intensity distribution) are not necessarily the same.

CL-810 fixed (steady-burning) red obstruction light
- Used primarily for night protection on smaller structures and for intermediate lighting on antennas of more than 45 m.

CL-856 high-intensity flashing white obstruction light, 40 flashes per minute (fpm)
- Used primarily for high structures and day protection on antennas where marking may be omitted.

CL-857 high-intensity flashing white obstruction light, 60 fpm
- Lighting of catenary crossings

CL-864 flashing red obstruction light, 20–40 fpm
- Used for night protection of extensive obstructions and antennas of more than 45 m.

CL-865 medium-intensity flashing white obstruction light, 40 fpm
- When operated 24 hr, paint marking may be omitted.

CL-866 medium-intensity flashing white obstruction light, 60 fpm
- White catenary lighting

CL-885 flashing red obstruction light, 60 fpm
- Red catenary light

6.5.1 Rotating Obstruction Light

The majority of flashing obstruction light units are of a strobe (capacitor discharge) design. An exception is one type of CL-865 medium-intensity flashing light, which is of a rotating design, i.e. the light display is produced by rotating lenses. Since this particular light unit might otherwise be mistaken for an aerodrome beacon, colour coding is used to produce a sequenced display of white, white, red, white, white, and red.

![Figure 6.2—Rotating Obstruction Light](image)

The rotating type CL-865 also has the same 20 000 candela intensity for nighttime as for daytime operation. The absence of dimming is allowed for two reasons: (1) the specified intensities are minimum requirements; and (2) the rotating characteristic does not produce glare for the pilot.

6.5.2 Tower Configurations

Depending on the height of the towers and other factors, the installation of lights on towers and antennas may vary as shown in Figure 6.3.

![Figure 6.3—Configurations of Lighting on Skeletal Structures](image)

</tbody>
</table>
6.6  APPURTENANCES

Where an obstruction is provided with a red obstruction lighting system, any appurtenance 12 m in height will require an obstruction light at the base of the appurtenance. Where such an appurtenance is more than 12 m in height, the light must be installed on the top of the appurtenance. If the appurtenance is not capable of carrying the light unit, the light may be mounted on the top of an adjacent mast.

Where a high-intensity white flashing lighting system is required, appurtenances higher than 12 m in height will require a top-mounted medium-intensity white flashing omnidirectional light unit.

6.7  SUSPENDED CABLE SPAN MARKINGS

Suspended cable spans, such as power line crossings, assessed as being hazardous to air navigation are normally marked with coloured balls suspended from a messenger cable between the tops of the support towers. The support towers are obstruction painted. When painting the support towers is not practical, or when additional warning is necessary, shore markers painted international orange and white will be displayed. In some cases, older marker panels that have not been updated are of a checkerboard design.

An alternative method of marking is to use strobe lights on shore-based cable support towers. Normally three levels of lights are installed as follows: one light unit at the top of the structures to provide 360° coverage; two light units on each structure at the lowest point of the arc of the lowest cable; and two light units at a point midway between the top and bottom levels with 180° coverage. The beams of the middle and lower lights are adjusted so that the signal will be seen from the approach direction on either side of the power line. The lights flash sequentially: middle lights followed by the top lights and then the bottom lights in order to display a “fly up” signal to the pilot. The middle light may be removed in the case of narrow power line sags; in this case the bottom lights will flash first then the top lights will flash in order to display a “fly up” signal to the pilot. When deemed appropriate by an aeronautical study, medium-intensity white flashing omnidirectional lighting systems may be used on supporting structures of suspended cable spans lower than 150 m above ground level (AGL).

Obstruction markings on aerial cables (i.e. marker balls) that define aeronautical hazards are generally placed on the highest line for crossings where there is more than one cable. Obstruction markings can also be installed on crossings under the Navigation Protection Act. In this case, the marker balls are placed on the lowest power line and are displayed to water craft as a warning of low clearance between the water and an overhead cable.

In accordance with the foregoing, pilots operating at low levels may expect to find power line crossings marked as either an aeronautical hazard or a navigable water hazard. They may be unmarked if it has been determined by the applicable department or agency that they are neither an aeronautical nor a navigable waters hazard. Pilots operating at low altitudes must be aware of these hazards and exercise extreme caution.

New technology has recently been developed so that obstacle lighting is only activated when required to alert pilots who are on a flight path that may lead to a collision with the obstacle. The system has economic benefits and addresses public complaints regarding light pollution.

The system uses radar to detect and track aircraft. The potential for collision with an obstacle is determined by the aircraft’s speed and angle of approach. If there is a risk of collision, the lighting turns on and an audio warning is broadcast on the very high frequency (VHF) radio. The lighting does not turn on until it is needed by the detected aircraft. Since the system uses radar, no additional equipment (e.g. a transponder) needs to be installed on board the aircraft.

The obstacle lighting is turned on and the audio warning is emitted approximately 30 s before the aircraft reaches the obstacle. In the case of catenaries, the audio warning will state “POWER LINE, POWER LINE”. For other types of obstructions, a different message will be sent. In some cases, such as those involving wind farms near aerodromes, an audio signal might not be provided, in order to avoid confusing pilots making an approach to landing.

Any questions or comments may be directed to the Transport Canada Flight Standards office in Ottawa (see GEN 1.1.1 for contact information).
7.0 AERODROME LIGHTING

7.1 GENERAL

The lighting facilities available at an aerodrome or airport are described in the Canada Flight Supplement (CFS). Information concerning an aerodrome or airport’s night lighting procedures is included as part of the description of lighting facilities, where routine night lighting procedures are in effect. Where night lighting procedures are not published for an aerodrome or airport, pilots should contact the aerodrome operator concerned and request that the appropriate lights be turned on to facilitate their intended night operations.

7.2 AERODROME BEACON

Many aerodromes are equipped with a flashing white beacon light to assist pilots in locating the aerodrome at night. The aerodrome beacon may be of the rotating or flashing type. The flash frequency of beacons at aerodromes or airports used by aeroplanes is 22 to 26 evenly spaced flashes per minute (fpm) for rotating beacons or 20 to 30 for flashing beacons.

The flash frequency of beacons at aerodromes and heliports used only by helicopters is sequenced to transmit the Morse code letter “H” (in groups of four quick flashes) at the rate of three to four groups per minute.

7.3 MINIMUM NIGHT LIGHTING REQUIREMENTS AT AERODROMES

Section 301.07 of the Canadian Aviation Regulations (CARs) requires that any area of land that is to be used as an aerodrome at night shall have fixed (steady) white lights to mark the runway, and fixed red lights to mark unserviceable (hazardous) areas.

Retroreflective markers may be substituted for lights to mark the runway at aerodromes, provided alignment lights are installed (see AGA 7.19). This alternative for night marking of runways, however, is not approved for certified sites.

7.4 UNSERVICEABLE AREA LIGHTING

Unserviceable areas within the manoeuvring area of an aerodrome being used at night are marked by steady burning red lights outlining the perimeter of the unserviceable area(s). Where it is considered necessary in the interest of safety, one or more flashing red lights may be used in addition to the steady red lights.

7.5 APPROACH LIGHTING

The approach lighting systems depicted in the Canada Flight Supplement (CFS) include the following:

7.5.1 Non-Precision Approach Runways

(a) Low Intensity Approach Lighting System (LIAL): This system is provided on non-precision approach runways and consists of aviation yellow fixed-intensity twin light units spaced at 60-metre intervals commencing 60 m from the threshold and extending back for a total distance of 900 m (terrain permitting).

(b) Omnidirectional Approach Lighting System (ODALS): This system is a configuration of seven omnidirectional, variable-intensity, sequenced flashing lights. An ODALS provides circling, offset, and straight-in visual guidance for non-precision approach runways. There are five lights on the extended centreline commencing 90 m from the threshold and spaced 90 m apart over a total distance of 450 m. Two lights are positioned 12 m to the left and right of the threshold. The system flashes towards the threshold, then the two threshold lights flash in unison; the cycle repeats once per second.

(c) Medium Intensity Approach Lighting System (MALSF) or Medium Intensity Approach Lighting System with Sequenced Flashing Lights (MALSFL): This system consists of seven barrettes of variable-intensity lights spaced 60 m apart, commencing 60 m from the threshold, over a distance of 420 m. In a MALSF, the three barrettes farthest away from the threshold contain a sequenced flashing light unit. These lights flash sequentially towards the threshold, repeating at two cycles per second.
Medium Intensity Approach Lighting System with Runway Alignment Indicator Lights (MALSR): This system consists of variable-intensity approach lights spaced 60 m apart, commencing at 60 m from the threshold, and extending 720 m. This system consists of the following:
(i) seven barrettes of light over a distance of 420 m;
(ii) one side barrette of light on each side of the centreline barrette at 300 m from the runway threshold; and
(iii) five sequenced flashing lights over the remaining distance of 300 m. These lights flash in sequence towards the threshold at a rate of two cycles per second.

The MALSR has the same configuration as the SSALR, but has lower intensity lights.

Simplified Short Approach Lighting System (SSALS): This system is the same as MALS (i.e. MALSF without the sequenced flashing lights) but high intensity lights are used instead. (See Figure 7.3 for the layout without the sequenced flashing lights.)

Precision Approach Runways

Simplified Short Approach Lighting System with Runway Alignment Indicator Lights (SSALR): This system is the same as the MALSR but high intensity lights are used instead. See Figure 7.4 for the layout.

Approach Lighting System with Sequenced Flashers—CAT II (ALSF-2): This system consists of rows of five white variable-intensity light units placed at longitudinal intervals of 30 m commencing 30 m from the threshold and extending for a total distance of 720 m. In view of the very low decision height associated with CAT II operations, the following additional lights are provided:
(i) runway threshold (green)
(ii) 150 m distance bar (white with red barrettes)
(iii) side barrettes (red)

7.6 VISUAL APPROACH SLOPE INDICATOR SYSTEMS (VASIS)

General

VASIS is a generic term referring to different approach slope indicators. Types of VASIS are VASI (visual approach slope indicator), AVASI (abbreviated VASI), PAPI (precision approach path indicator), and APAPI (abbreviated PAPI).

A VASIS consists of a series of lights visible from approximately 4 NM and designed to provide visual indications of the desired approach slope to a runway (usually 3°). At a certified airport, aircraft following the on-slope signal are provided with safe obstruction clearance to a minimum of 6° on either side of the extended runway centreline out to 7.5 km (4.1 NM) from the runway threshold. Newly certified airports are commonly protected out to 8° on each side of the extended runway centreline. Exceptions will be noted in the CFS. Descent using VASIS should not be initiated until the aircraft is visually aligned with the runway centreline.

The vertical distance from a pilot’s eyes to the lowest portion of the aircraft in the landing configuration is called the eye-to-wheel height (EWH), and this distance varies from less than 10 ft (3 m) up to 45 ft (14 m) for some wide-bodied aircraft, such as the B-747. Consequently, approach slope indicator systems are related to the EWH for critical aircraft, and they provide safe wheel clearance over the threshold when the pilot is receiving the on-slope indication.

Pilots and/or air operators should ensure that the VASIS type to be used is appropriate to the given aircraft type, based on the EWH for that aircraft. If this information is not already available in the AFM or other authoritative aircraft manuals (e.g. the flight crew operating manual), the aircraft manufacturer should be contacted.

CAUTION:
Incompatibility between the EWH and the VASIS type could result in decreased terrain clearance margins and in some cases, even premature contact with terrain (e.g. a CFIT accident).

The Canadian civil aviation standard for VASIS is the PAPI. Some airports still have the older systems of VASI. The VASI and PAPI light units have the same purpose of descent indication with respect to an approach corridor but are arranged in a different pattern, as shown below.
The VASI and PAPI have lights normally situated on the left side of the runway only. When available strip widths preclude the use of a full system, an abbreviated approach slope indicator, AV or AP, consisting of only two light units, may be installed.

Where a PAPI or VASI is provided on a precision approach runway and has not been harmonized with a vertical guidance signal, it will be turned off in weather conditions involving a ceiling of less than 500 ft (150 m) and/or visibility less than 1 mi., unless specifically requested by the pilot. This is to avoid possible contradiction between the electronic precision approach vertical guidance and visual (VASI/PAPI) glide slope signal.

### 7.6.2 Visual Approach Slope Indicator (VASI) V1 and V2 and Abbreviated VASI (AVASI) AV

The VASI (V1 and V2) consists of four light units situated on the left side of the runway in the form of a pair of wing bars (two light units per wing bar), referred to as the upwind and downwind wing bars. Each light unit of a wing bar projects a beam of light. The upper part of the beam shows white while the lower part shows red. When the pilot is:

(a) above the approach slope, both upwind and downwind bars show white.

(b) on the approach slope, the upwind bar shows red and the downwind bar shows white.

(c) below the approach slope, both upwind and downwind bars show red.

(d) well below the approach slope, the lights of the two wing bars merge into one red signal.

The AVASI (AV) consists of two light units situated on the left side of the runway in the form of a pair of wing bars (one light unit per wing bar). The display is similar to that of a VASI and depends on the position of the pilot’s eyes.

### 7.6.3 Precision Approach Path Indicator (PAPI) and Abbreviated PAPI (APAPI)

PAPI consists of four light units typically situated on the left side of the runway in the form of a wing bar. When the pilot is:

(a) well above the approach slope, all four units show white.

(b) slightly above the approach slope, the one unit nearest the runway edge shows red and the other three show white.

(c) on or close to the approach slope, the two units nearest the runway edge show red and the two units farthest from the runway edge show white.

(d) slightly below the approach slope, the three units nearest the runway edge show red and the other shows white.

(e) well below the approach slope, all four units show red.

APAPI consists of two light units situated on the left side of the runway in the form of a wing bar. When the pilot is:

(a) above the approach slope, both units show white.

(b) on or close to the approach slope, the unit nearer to the runway edge shows red and the unit farther from the runway edge shows white.

(c) below the approach slope, all units show red.

---

CAUTION: **Lens Contamination**—The PAPI/APAPI light box is a sealed design with a front lens or cover glass. When the temperature of the PAPI/APAPI unit lens or cover glass descends below the dew point, frost or condensation may occur depending on the season. Frost or condensation contamination may produce a false signal by mixing the red and white colours of the beam. Under these conditions, the relative intensities of the red and white portions of the beam may cause the mixture to
be perceived as predominantly white in colour for a period of time after the PAPI/APAPI is first turned on. Since the mixture may be interpreted as a fly-down signal, the pilot should be aware of other cues (e.g. the runway perspective) so as to avoid descent below the OPS. When the PAPI/APAPI provides a true signal, it should display a crisp transition from white to red as the aircraft descends through the sectors. If contamination is suspected, flight crews are advised to disregard the PAPI/APAPI display.

### 7.6.4 Categories According to Eye-To-Wheel Height (EWH) in the Approach Configuration

#### 7.6.4.1 General

VASIS are categorized according to the EWH in the approach configuration, as shown in Tables 7.1 and 7.2 below. Where a VASIS is given for a published category, it is intended to be useable by all aircraft within the stated EWH group unless otherwise stated.

**NOTE:**
The EWH is the vertical distance in-flight of the eye path to the wheel path, as shown in Figure 7.8, and is determined by the approach slope angle and the pitch angle for the maximum certified landing weight at \( V_{\text{ref}} \). This should not be confused with the horizontal and vertical dimensions as may be measured when the aircraft is on the ground.

#### 7.6.4.2 Visual Approach Slope Indicator (VASI) Categories

The VASI installations are designed according to aircraft height group categories AV, V1, and V2, as indicated in Table 7.1. The greater the value of the EWH in the approach configuration, the farther the VASI is installed upwind from the threshold to provide the appropriate MEHT.

<table>
<thead>
<tr>
<th>Category</th>
<th>System</th>
<th>Aircraft height group EWH in the approach configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>AV</td>
<td>AVASI</td>
<td>0 ft (0 m) ≤ EWH &lt; 10 ft (3 m)</td>
</tr>
<tr>
<td>V1</td>
<td>VASI</td>
<td>0 ft (0 m) ≤ EWH &lt; 10 ft (3 m)</td>
</tr>
<tr>
<td>V2</td>
<td>VASI</td>
<td>10 ft (3 m) ≤ EWH &lt; 25 ft (7.5 m)</td>
</tr>
</tbody>
</table>

#### 7.6.4.3 Precision Approach Path Indicator (PAPI) Categories

PAPI and APAPI installations are designed for aircraft height group categories AP, P1, P2, and P3, as indicated in Table 7.2. The greater the value of the EWH in the approach configuration, the farther the PAPI is installed upwind from the threshold to provide the appropriate MEHT.

<table>
<thead>
<tr>
<th>Category</th>
<th>System</th>
<th>Aircraft height group EWH in the approach configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>AP</td>
<td>APAPI</td>
<td>0 ft (0 m) ≤ EWH &lt; 10 ft (3 m)</td>
</tr>
<tr>
<td>P1</td>
<td>PAPI</td>
<td>0 ft (0 m) ≤ EWH &lt; 10 ft (3 m)</td>
</tr>
<tr>
<td>P2</td>
<td>PAPI</td>
<td>10 ft (3 m) ≤ EWH &lt; 25 ft (7.5 m)</td>
</tr>
<tr>
<td>P3</td>
<td>PAPI</td>
<td>25 ft (7.5 m) ≤ EWH &lt; 45 ft (14 m)</td>
</tr>
</tbody>
</table>

The aircraft position with respect to the PAPI display is shown in Figure 7.8. The approach corridor is defined by the setting angles of light units C and B. The MEHT is defined by the angle M, which is 2 min of arc below the angle B. This accounts for the pilot’s difficulty in discerning when the transition from white to full red has occurred. The available MEHT is the sum of the EWH in the approach configuration and the prescribed wheel clearance. The distance D for the location of the PAPI from the threshold is calculated using the tangent of the angle M. In other words, \( D = \text{MEHT}/\tan(M) \).

For more information about wheel clearance, see Aerodromes Standards and Recommended Practices (TP 312).

#### 7.6.5 Knowing the Eye-to-Wheel Height (EWH)

For a particular category of PAPI and aircraft group, there is an available wheel clearance. This is why knowing the EWH in the approach configuration is important. For example, if your aircraft belongs in the aircraft height group for a P3 PAPI, using a P2 PAPI means having much less wheel clearance at threshold crossing. Figure 7.8 also shows why flying below the approach corridor (with the lights showing three red and one white) is not recommended.

#### 7.6.6 Obstacle Protection Surface (OPS)

For certified aerodromes, the installation of a PAPI or an APAPI requires the establishment of an obstacle protection surface (OPS). The OPS provides a buffer below unit angle A, which, for PAPI, is the transition from one white light and three red lights to four red lights, and for APAPI, is the transition from one white light and one red light to two red lights, as shown in Figure 7.9. Objects do not penetrate the OPS. Where an object or terrain protrudes above the OPS and beyond the length of the approach OLS, one of a number of
possible measures may be taken such as raising the approach slope, moving the PAPI further upwind of the threshold, or reducing the operational length of the OPS and marking/lighting the obstacle. At some aerodromes, particularly in mountainous regions, a limitation is established as a PAPI usable distance from the threshold and is published in the CFS. The PAPI signal is not to be used until the aircraft is within that specified distance. For more information about OPS dimensions, see Aerodromes Standards and Recommended Practices (TP 312).

7.8 Runway Lighting

A runway on an aerodrome that is used at night shall display two parallel lines of fixed white lights visible for at least 2 mi. to mark take-off and landing areas. These lights are arranged so that:

(a) the lines of lights or markers are parallel and of equal length and the transverse distance between the lines is equal to the runway width in use during the day;

(b) the distance between adjacent lights or markers in each line is the same and is not more than 60 m (200 ft);

(c) each line of lights or markers is not less than 420 m (1 377 ft) in length and contains no fewer than eight lights or markers; and

(d) each light or marker in a line of lights or markers is situated opposite to a light or marker in the line of lights or markers on the other side of the runway, so that a line connecting them forms a right angle to the centreline of the runway.

For a certified aerodrome, runway lighting may include centerline and touchdown zone lighting depending on runway visibility and approach category.

7.8.1 Runway Edge Lights (REDL)

These are variable-intensity white lights at the runway edges along the full length of the runway spaced at maximum intervals of 60 m, except at intersections with other runways. On some runways, a 600-m section of lights or the last third of the runway at the remote end—whichever is shorter—may show yellow. The units are light in weight and mounted in a frangible manner.

7.8.2 Runway Threshold and End Lights

Runway threshold/end indication is provided by green and red light units respectively, in the form of a pair of bars along the threshold on each side of the runway centreline, where there is an ODALS or where no approach lighting is provided. Red shows in the direction of takeoff and green shows in the approach direction.

Where approach lighting other than ODALS is provided, an approach threshold bar that extends across the full width of the runway forms part of the approach lighting configuration. Figure 7.11 shows the different configurations of such lights. Runway end lights are always provided. Runway threshold lights are independent from approach threshold bar lights and are only lit if the approach threshold bar is not lit.

Where MALSR, MALSF or MALS is provided, the green threshold lighting is physically separated from the approach threshold bar due to difference in light intensities and circuitry.
Where ALSF-2, SSALR or SSALS is provided, the runway threshold lights form part of the approach threshold bar configuration (opposite the runway end lights).

Where an ALSF-2 is provided, the green threshold lighting is extended farther as wing bars to each side of the runway.

Figure 7.11—Runway Threshold and End Lights

7.9 Threshold Lighting Displacement

Where runway thresholds have been displaced from the beginning of the runway, the runway threshold lights and the approach threshold bar are displaced accordingly, using inset lights for approach threshold bars and wing bar lights for runway threshold lights, as follows:

Figure 7.12—Threshold Lighting Displacement

7.10 Runway Centreline Lighting

Runway centreline lighting is provided on CAT II and CAT III runways. It consists of variable-intensity lights installed on the runway surface spaced at intervals of 15 m. The lights leading in the take-off or landing direction are white to a point 900 m from the runway end. They then change to white and red until 300 m from the runway end, at which point they become red.

7.11 Runway Touchdown Zone Lighting

Touchdown zone variable intensity white lights are provided on CAT II and CAT III instrument runways. They consist of bars of three inset lights per bar disposed on either side of the runway centreline, spaced at 30 m intervals commencing 30 m from the threshold, extending 900 m down the runway. The lights are unidirectional, showing in the direction of approach to landing.

Figure 7.13—Runway Touchdown Zone Lighting

7.12 Rapid-Exit Taxiway Lighting

Rapid-exit taxiway lights are alternating green and yellow in colour and are installed on the runway surface commencing approximately 60 m before the turn and continuing with the alternating colours until beyond the HOLD position. Once beyond the HOLD position, the colour pattern reverts to continuous green.

7.13 Taxiway Lighting

Taxiway edge lights are blue in colour and are spaced at maximum intervals of 60 m. Where a taxiway intersects another taxiway or a runway, two adjacent blue lights are placed at each side of the taxiway where no fillet or curve is provided. To facilitate the identification of the taxiway entrance on departure from the apron, the intersection of an apron with a taxiway is indicated by two adjacent yellow lights at taxiway/apron corners.

Taxiway centreline lights are green in colour and are installed on the taxiway surface. They are spaced at 15-m intervals with less spacing on taxiway curves.
7.14 **Stop Bars**  
Stop bars are provided at every taxi-holding position serving a runway when it is intended that the runway will be used in visibility conditions below RVR1200 (¼ SM). Stop bars are located across the taxiway at the point where it is desired that traffic stop and consist of lights spaced at intervals of 3 m across the taxiway. They appear showing red in the intended direction of approach to the intersection or taxi-holding position.

Where the stop bar is collocated with taxiway centreline lighting, a 90-m segment of the taxiway centreline lighting beyond the stop bar is turned off when the stop bar is illuminated. The stop bar is illuminated again after a timed duration or by means of sensors installed on the taxiway.

One should never cross an illuminated stop bar, even with a clearance from ATC.

![Figure 7.14—Stop Bar Lighting](image)

7.15 **Runway Guard Lights**  
Runway guard lights are provided at each taxiway/runway intersection to enhance the conspicuity of the holding position for taxiways supporting runway operations below a visibility value of RVR2600 (½ SM). They consist of yellow unidirectional lights that are visible to the pilot of an aircraft taxiing to the holding position, but their configuration may vary:

(a) They can consist of a series of lights spaced at intervals of 3 m across the taxiway. Where this is the case, the adjacent lights illuminate alternately and even lights illuminate alternately with odd lights.

(b) They can consist of two pairs of lights, one on each side of the taxiway adjacent to the hold line. Where this is the case, the lights in each unit illuminate alternately.

7.16 **Heliport Lighting**  
Where a heliport is used at night, the perimeter of the TLOF may be lighted by yellow perimeter lights or by floodlighting.

(a) *Yellow perimeter lights:* Where the TLOF is circular, no fewer than eight yellow lights are used to mark the perimeter. In a rectangular layout, the perimeter is marked by a minimum of four yellow lights on each side, with a light at each corner.

(b) *Floodlighting:* When provided, the floodlighting will illuminate the TLOF such that the perimeter marking of the TLOF is visible. Floodlight units will be located beyond the perimeter of the FATO.

NOTE:  
Perimeter lighting or reflective tape may be used in addition to floodlighting.

![Figure 7.15—Examples of TLOF Lighting](image)

7.16.1 **Final Approach and Take-Off (FATO) Lighting**  
A FATO perimeter is marked by white or green lights in the same configuration as TLOF perimeter lighting. Where a TLOF is not located within a FATO, the aiming point will be defined by at least seven red aeronautical ground lights located on the triangular marking.
FATO or TLOF perimeter lights may be LEDs. Consult the CFS for verification of lighting type.

**CAUTION:**

Heliports using LED lighting systems may not be visible when certain NVIS equipment is employed. This is an operational limitation of the NVIS equipment, as the purpose of heliport lighting is to be viewed by the naked eye.

Candela values for heliport lighting systems are detailed in ICAO Annex 14, Volume II.

---

### 7.18 Aircraft Radio Control of Aerodrome Lighting (ARCAL)

ARCAL systems are becoming more prevalent as a means of conserving energy, especially at aerodromes and airports not staffed on a continuous basis or where it is not practicable to install a land line to a nearby FSS. Aside from obstacle lights, some or all of the aerodrome and airport lighting may be radio-controlled.

Control of the lights should be possible when aircraft are within 15 NM of the aerodrome or airport. The frequency range is 118 to 136 MHz.

Activation of the system is via the aircraft VHF transmitter and is effected by depressing the push-to-talk button on the microphone a given number of times within a specified number of seconds. Each activation will start a timer to illuminate the lights for a period of approximately 15 min. The timing cycle may be restarted at any time during the cycle by repeating the specified keying sequence. It should be noted that ARCAL Type K runway identification lights (code AS) can be turned off by keying the microphone three times on the appropriate frequency. The code for the intensity and the lighting period varies for each installation. Consequently, the CFS must be consulted for each installation.

**NOTE:**
Pilots are advised to key the activating sequence when commencing their approach, even if the aerodrome or airport lighting is on. This will restart the timing cycle so that the full 15-min cycle is available for their approach.

### 7.19 Retroreflective Markers

Some aerodromes may use retroreflective markers in place of lights to mark the edges of runways or helipads. These retroreflective markers are approved for use on runways at registered aerodromes only; however, they may be used as a substitute for edge lighting on taxiways or apron areas at some certified airports.

Retroreflective markers are to be positioned in the same manner as runway lighting described in earlier paragraphs of this chapter. Therefore, when the aircraft is lined up on final approach, retroreflective markers will provide the pilot with the same visual presentation as normal runway lighting. A fixed white light or strobe light shall be installed at each end of the runway to assist pilots in locating the aerodrome and aligning the aircraft with the runway. Similarly, retroreflective markers at heliports are to be positioned in the same pattern as prescribed for helipad edge lighting.

The approved standard for retroreflective markers requires that they be capable of reflecting the aircraft landing lights so that they are visible from a distance of 2 NM. Pilots are cautioned that the reflective capabilities of retroreflective markers are greatly affected by the condition of the aircraft landing lights, the prevailing visibility and other obscuring conditions.
weather phenomena. Therefore, as part of pre-flight planning to an aerodrome using retroreflective markers, pilots should exercise added caution in checking the serviceability of their aircraft landing lights and making provision for an alternate airport with lighting in case of an aircraft landing light failure.

8.0 AIRCRAFT RESCUE AND FIRE FIGHTING (ARFF)

8.1 GENERAL

Aircraft rescue and firefighting (ARFF) service is provided at some airports in accordance with the criteria stated in CAR 303. The primary responsibility of an ARFF service is to provide a fire-free egress route for the evacuation of passengers and crew.

8.2 AIRCRAFT RESCUE AND FIRE FIGHTING (ARFF) HOURS OF AVAILABILITY

The aerodromes or airports providing ARFF publish the hours during which an ARFF service is operated in the CFS under the ARFF annotation.

8.3 CLASSIFICATION SYSTEM

Table 8.1 identifies the critical category for firefighting as it relates to the aircraft size, the quantities of water and complementary extinguishing agents, the minimum number of ARFF vehicles and the total discharge capacity. For ease of interpretation, the table is a combination of the two tables found under CAR 303.

</tbody>
</table>
8.4 AIRCRAFT RESCUE AND FIRE FIGHTING (ARFF) STANDBY REQUEST

Local standby means the level of response when an aircraft has, or is suspected to have, an operational defect. The defect would normally cause serious difficulty for the aircraft to achieve a safe landing.

Full emergency standby means the level of response when an aircraft has, or is suspected to have, an operational defect that affects normal flight operations to the extent that there is possibility of an accident.

When informed that an emergency has been declared by a pilot, the airport ARFF unit will take up emergency positions adjacent to the landing runway and stand by to provide assistance. Once response to an emergency situation has been initiated, the ARFF unit will remain at the increased state of alert until informed that the pilot-in-command has terminated the emergency. After the landing, ARFF will intervene as necessary and, unless the pilot-in-command authorizes their release, escort the aircraft to the apron and remain in position until all engines are shut down.

In order to adequately respond, a pilot request to “stand by in the fire hall” is not appropriate. Pilots are reminded, however, that the ARFF unit will terminate their alert posture when informed by the pilot that the emergency situation no longer exists.

8.5 AIRCRAFT RESCUE AND FIRE FIGHTING (ARFF) DISCREET COMMUNICATION

The capability to communicate on a discreet frequency is normally available at airports that provide ARFF services.

9.0 AIRCRAFT ARRESTING SYSTEMS

9.1 ENGINEERED MATERIAL ARRESTING SYSTEMS (EMAS)

EMAS is an arresting system designed for transport category aeroplanes in the event of a runway overrun. An EMAS bed is designed to stop an overrunning aeroplane by exerting predictable deceleration forces on its landing gear as the EMAS material crushes.

9.1.1 System Description

The strength of the arrester bed is designed to decelerate the aeroplane without structural failure to the landing gear. The beds are made up of a grouping of blocks of crushable cellular concrete that will reliably and predictably crush under the weight of an aeroplane.

In order to arrest an aeroplane overrunning a runway end, EMAS beds are placed beyond the end of a runway and in alignment with the extended runway centerline.

9.1.2 System Depiction

The aerodrome sketch will show the location and dimensions of the EMAS beds. In the example below, the EMAS bed is shown as an outlined box with diagonal lines running through it. The dimensions are provided in feet.

9.1.3 Pilot Considerations for Engagement

Prior to using a runway, pilots should be aware of the presence of an EMAS bed. Pilots should review the aerodrome sketch and other aerodrome information to determine if the runway that they will be using is equipped with an EMAS.

During the take-off or landing phase, if a pilot determines that
the aeroplane will exit the runway end and enter the EMAS, the following procedure should be followed:

(a) continue to follow rejected-takeoff procedures or, if landing, maximum-braking procedures outlined in the aircraft flight manual, regardless of aeroplane speed upon exiting the runway;

(b) continue straight ahead—do not veer left or right. Having all of the aeroplane’s landing gear enter the bed will maximize the EMAS’s stopping capability. Veering to the side may result in the aeroplane missing the bed altogether or having only one set of wheels enter the bed with reduced effectiveness. The quality of deceleration will be best within the confines of the bed. The further the aeroplane travels into the bed, and into deeper concrete, the greater the deceleration;

(c) do not take any action—the arrester bed is a passive system, similar to other traditional arresting systems such as cables, chains and aircraft netting;

(d) do not attempt to taxi or otherwise move the aeroplane once stopped;

(e) use standard aircraft emergency ground egress procedures, should an emergency egress be required. Where the surface of the bed has been breached, the loose material will crush underfoot. During egress, it is important to note that the two sides and the back of the arrester bed have continuous steps built in to help provide easy access for responding ARFF vehicles and to enable passengers to safely step off the bed; and

(f) use slides or aircraft stairs to deplane passengers after an EMAS arrestment as the EMAS bed will not provide a stable base for the air stairs.

9.2 MILITARY AIRCRAFT ARRESTING SYSTEMS

9.2.1 Background

Some civil airports and military aerodromes are equipped with aircraft arresting systems. An aircraft arresting system usually consists of two sets of gear, called energy absorbers, with one located on each side of the runway, normally approximately 460 m from the threshold. These energy absorbers are interconnected by an arrester cable, which is attached to a nylon tape that is wound onto a tape storage drum (reel) on each energy absorber. In order to locate the energy absorbers away from the edge of the runway, runway edge sheaves are located next to the runway edge. The runway edge sheaves act as a guide (pulley) for the tape and have sloped sides to permit an aircraft to roll over them.

When the tailhook of a fighter aircraft engages the cable, the tape storage drums start to turn. The energy absorbers apply a braking force to the storage drums, which in turn slows the aircraft and brings it to a stop.

9.2.2 Markings

For identification, yellow circles are painted across the runway at the location of the aircraft arrester cable. A lighted sign with a yellow circle beside the runway marks the location during darkness.

9.2.3 Operations

At civil airports, civil aeroplane operations will not be permitted while the arrester cable is deployed across the runway. At military aerodromes, civil aeroplane operations may be permitted with the arrester cable deployed across the runway.

9.2.4 Damage Hazards

(a) Cables: Pilots are advised to avoid crossing the aircraft arrester cable at speeds in excess of 10 mph, as a wave action may develop in the cable, which could damage the aircraft. This is particularly important for nose-wheel aircraft having minimal propeller or undercarriage-door clearance, or wheel fairings. Tail-wheel aircraft may also sustain damage if the tail wheel engages the cable.

(b) Runway edge sheaves: The runway edge sheaves are located next to the runway edge, on the runway shoulder, and they are above grade. The two sides perpendicular to the runway are sloped, but the other two sides, parallel to the runway, are vertical. The runway edge sheaves are not frangible and may cause damage to an aeroplane that contacts or rolls over one.

(c) Energy absorbers: The energy absorbers are normally located beside the graded area of the runway strip (at a distance greater than 61 m from the runway centreline). The energy absorbers are not frangible and will cause damage to an aeroplane that contacts one.

9.2.5 Information for Pilots

Pilots will normally be advised of the status of the arrester cable through ATIS or by ATC. The existence of an aircraft arresting system should be included in the runway data section of the CFS. The location of an aircraft arresting system should also be depicted on the aerodrome sketch.
